1. INTRODUCTION AND SUMMARY

1.1 MISSION PROFILE SUMMARY

The revised preliminary mission planning trajectory described in this document is designed for a manned-configured spacecraft on Apollo Applications Mission AAP-1/AAP-2. This will be a dual launch mission with an unmanned vehicle (AAP-2) being launched approximately 1 day after the launch of a manned-configured spacecraft (AAP-1).

The basic purposes of Mission AAP-1/AAP-2 include the following:

- a) Demonstration of the capability of the orbital workshop (an S-IVB stage fitted with an airlock) when docked to a command service module (CSM) to provide a habitable environment for astronaut activity to complete a mission of up to 28 days from the time of initial launch of AAP-1
- b) Provision of an orbital workshop which can be stored in orbit for a period up to 1 year and will be capable of reactivation and rehabitation for long duration missions anytime within that period when resupplied
- c) Demonstration of the feasibility of a long duration (up to 28 days) manned spaceflight mission by use of expendables carried external to the CSM
- d) Medical, technological, engineering, scientific, and applications experiments conducted in earth orbit that contribute to future space applications

For simulation purposes, the AAP-1 launch is assumed to occur on 15 January 1969, at 21:00 hours Greenwich Mean Time (GMT) (4:00 p.m. Eastern Standard Time) from Launch Complex 34 at Cape Kennedy, Florida. This late afternoon launch time was selected in order to insure daylight recovery of the AAP-1 CM at termination of the anticipated 28 day mission. *AAP-2 would be launched from Launch Complex 37B on 16 January 1969, 23 hours 24 minutes 15 seconds after the lift-off of AAP-1.

It was assumed that this launch time, which satisfies this constraint in the PMP, would also satisfy the constraint in the revised PMP, but it does not (Section 1.2.5).

The mission profile has been divided into four periods of activity.

These periods, and the corresponding significant mission events, are as follows:

- a) First period of activities (00:00:00:00 to 00:23:24:15, g.e.t. in day:hour:minute:second)
 - 1) AAP-1 ascent to orbit inserting the S-IVB/CSM into a 81-by 110-nautical mile elliptical orbit
 - 2) CSM separation from the S-IVB; circularization of the CSM orbit at a 110-nautical mile altitude by use of the SPS at second apogee
 - 3) CSM coast until AAP-2 lift-off
- b) Second period of activities (00:23:24:15 to 01:04:09:41, g. e. t.)
 - 1) AAP-2 ascent to orbit inserting the unmanned modified S-IVB/airlock orbital workshop into a 260- by 260-nautical mile circular orbit, which is immediately altered to a 257- by 270-nautical mile elliptical orbit due to passivation of the S-IVB
 - 2) CSM active rendezvous
 - 3) CSM docking with orbital workshop
 - 4) CSM/orbital workshop coast phase
- c) Third period of activities (01:04:09:41 to 25:03:00:00, g.e.t.) orbital workshop experiments to 25th day.
- d) Fourth period of activities (25:03:40:00 to 25:10:00:21.7, g.e.t.)
 - 1) CSM/orbital workshop separation
 - 2) CSM deorbit maneuver
 - 3) CM entry

1. 2 MISSION PROFILE EVALUATION

The objective of this Revised Preliminary Mission Profile is to present a realistic sequence of mission events which attempts to satisfy

the mission requirements and constraints as defined in Reference 1.

Problem areas that were described in the Preliminary Mission Profile
(Reference 2) and the analysis of these problems will be discussed in this section.

1. 2. 1 Launch Vehicle Performance

The Preliminary Data Specification (Reference 3) defines the total and component weights of the AAP-1 and AAP-2 vehicles (Table 1). The Lunar Mapping and Surveying System and its associated experiments have been deleted from the AAP-1/2 mission, reducing the total weight by 4000 pounds. However, provisions are made on the service module to accomodate an additional 2383 pounds of RCS propellant (Section 1.2.4). The result is a net weight decrease of 1617 pounds for AAP-1. This decrease is the only significant change to the AAP-1 vehicle. The only significant change to the AAP-2 vehicle is the addition of the eight solar array panels, the total weight of which is 2741 pounds. Hence, the net weight of the AAP-2 vehicle is increased by this amount. The new launch weights and payloads of both vehicles were compared with the launch vehicle payload capabilities of the Uprated Saturn I launch vehicle quoted by MSFC, and found to be compatible.

1.2.2 S-IVB Passivation

Another area that was considered critical concerned the effects of propulsive vents during the S-IVB passivation sequence on the rendezvous operation. The analysis of this problem resulted in the decision to passivate the S-IVB immediately after insertion and prior to the initiation of the rendezvous maneuvers. The propulsive venting is done with the S-IVB pitched up 72 degrees causing the insertion orbit to become slightly elliptic.

1.2.3 S-IVB Instrumentation Unit Lifetime

The operational lifetime of the S-IVB instrumentation unit as stated in the PMP remains unchanged at 7.5 hours. It is desired to have the CSM complete the docking maneuver with the orbital workshop while the workshop has an attitude control capability. However, the attitude control capability exists only while the instrumentation unit is operational.

Deletion of the Lunar Mapping and Survey System and its associated docking and extraction maneuvers with the CSM and docking with the multiple docking adaptor resulted in reducing the time of docking maneuver completion from 14.5 hours (PMP) to 4 hours following AAP-2 lift-off. This reduction in time insures the attitude control capability of the OWS during the CSM OWS docking maneuver.

1. 2. 4 Service Module RCS Propellant Deficit

The SPS propellant requirements for the AAP-1/2 mission are well below the maximum quantity that the Block II service module propellant tanks can accommodate. However, the SM RCS propellant requirements are far above the propellant storage capability. Because of the above, the service module propellant tankage system modification was necessary. This modification consists of removing a portion of the SPS tankage system and adding a supplementary RCS tankage system, increasing the RCS propellant quantity from 1200 pounds to 3583 pounds. This modification allows the RCS propellant requirements for the AAP-1/2 mission to be satisfied (Table 2).

1. 2. 5 Recovery Area Lighting Conditions

The preliminary mission profile designed for the AAP-1/2 mission results in unsatisfactory splashdown lighting conditions in the Western Atlantic recovery zone after the 25th day of the mission. The recovery area lighting constraint as stated in Reference 4 restricts splashdown to no earlier than 1 hour prior to sunrise and no later than 1 hour prior to sunset. This constraint insures daylight recovery operations. The AAP-1/2 mission presented in this document is terminated after 25 days and splashdown occurs 40 minutes prior to sunrise, (Figure 1), thus satisfying the stated constraint. For each succeeding deorbit opportunity, the time between splashdown and sunrise increases by approximately 36 minutes, thereby failing to satisfy the daylight recovery constraint. The assumed launch time for the AAP-1 vehicle is 21:00 hours (GMT) (4:00 p. m. Eastern Standard Time); therefore, the mission duration cannot be extended by a later launch time without violating the launch abort in daylight constraint, Reference 4. It can be concluded that a 28-day mission is incompatible with the stated launch and recovery lighting constraints; however, a 25-day mission does satisfy these constraints.

2. MISSION OBJECTIVES AND MISSION REQUIREMENTS

2.1 MISSION OBJECTIVES

The following mission objectives for AAP-1/2 were taken from the Preliminary Mission Requirements document for Missions AAP-1 through 4 (Reference 1). These objectives have not been published in an official document but are based on the latest information available and are presented for information purposes only.

2.1.1 Primary

- a) Conduct long duration mission (up to 28 days) using a spent S-IVB stage (orbital workshop), an airlock, an MDA, and an Apollo CSM. The mission is intended to perform the following tasks:
 - 1) Evaluate effects of the long duration mission on CSM/S-IVB airlock systems and subsystems
 - 2) Evaluate space flight environmental effects on the crew and determine human task performance capability during the long duration mission
 - 3) Demonstrate hard-dock of the CSM to the MDA
 - 4) Demonstrate passivation of the spent S-IVB stage and activation of the workshop as a habitable space structure
 - 5) Verify the ability of mission ground support systems to support mission activities of extended duration
- b) Leave assembly in orbit for reactivation and reuse up to 1 year later

2.1.2 Secondary

Conduct experiments in the areas of science, applications, biomedical, technology, and engineering

2.2 MISSION REQUIREMENTS

The following mission requirements for AAP-1/2 were taken from the Preliminary Mission Requirements document for Missions AAP-1 through 4.

(Reference 1). The mission requirements have not been published in an official document but are presented as they are presently defined.

- a) AAP-1 will be launched from Complex 34 on a flight azimuth which results in an inclination that will provide compatible launch windows for AAP-2 launched 1 day later from Complex 37B. Provisions must also be considered to provide compatible launch windows for Mission AAP-3/AAP-4 up to 1 year later.
- b) The initial orbit for AAP-2 must be of sufficient altitude to provide a minimum of 1-year lifetime (-2σ) considering random orbital stabilization for the first month of operation, gravity gradient stabilization during all storage modes, and sun referenced stabilization during the AAP-3/4 mission.
- c) The CSM shall be hard docked during all attitude maneuvers, during crew transfer, and throughout periods when umbilicals are connected between the CSM and MDA/airlock.
- d) The S-IVB passivation will be accomplished automatically insofar as possible. A manual backup capability is required. Venting of LH₂ and LOX on the S-IVB will be non-propulsive (maximum 2 feet per second Δ V) following the initial vent immediately after orbital insertion and insertion until after docking of the CSM to the MDA.
- e) The S-IVB/IU for AAP-2 shall provide attitude control for CSM docking to the MDA. If the AAP-S-IVB/IU 7 1/2-hour attitude control lifetime is insufficient for the mission, either an increased lifetime for the present system or the use of the auxiliary attitude stabilization system will be required.
- f) Ground monitoring of the AAP-1/AAP-2 is required throughout the mission. Monitoring during the latter stage should be of similar magnitude to that of the early phase of the mission.
- g) The AAP-1/AAP-2 mission duration shall be planned for up to 28 days referenced from the AAP-1 launch to splashdown of the AAP-1 CM.
- h) A backup deorbit capability for the CSM is required.
- i) There will be no maneuvering of the orbital assembly using the CSM-SPS.

3. SUMMARY OF INPUT DATA

The data presented in this section were obtained from References 2, 3, 5, 6, 7, and 8 and from technical coordination meetings of MSC and TRW personnel. Included in this section are those MSFN and spacecraft specifications that form the basis for the preliminary mission planning of the Apollo Applications Mission AAP-1/AAP-2.

3.1 SATURN LAUNCH VEHICLE

The Uprated Saturn I launch vehicle which will be used to insert both the AAP-1 and AAP-2 payloads into initial earth orbit is comprised of the S-IB and S-IVB stages. The ascent-to-orbit trajectories upon which the preliminary mission planning is based were generated from Saturn IB launch vehicle configurations presented in the AS-207 and the AS-208 launch vehicle reference trajectories (References 5 and 6). These launch vehicle configurations are representative of those to be used for AAP-1 and AAP-2, respectively.

3.2 AAP-1 and AAP-2 SPACECRAFT

The AAP-1 spacecraft consists of a Block II Apollo CSM with modifications and an operational spacecraft LM adapter (SLA). The unmanned AAP-2 spacecraft, or orbital workshop, consists of a spent modified S-IVB stage, a SLA, the airlock (carried in the SLA on the LM attach points), a MDA and a nosecone. The AAP-2 vehicle and the combined AAP-1/AAP-2 configuration are illustrated in Figures 2, 3, and 4. The spacecraft data and specifications required to support this preliminary mission planning are presented in the following subsections.

3.2.1 Weight Characteristics

The spacecraft weight characteristics were obtained from Reference 3. These data are summarized in Table 1.

3.2.2 Performance Characteristics

The performance characteristics of the SM-RCS were obtained from Reference 2. In this preliminary mission planning, the RCS was used primarily for translational maneuvers. Such maneuvers are assumed

to require four thrusters; the performance characteristics of a single RCS thruster are shown in Table 3. The performance characteristics of the SPS were obtained from Reference 3 and are summarized in Table 4.

3.2.3 Reentry Aerodynamic Characteristics

The pertinent aerodynamic characteristics during reentry of AAP-1 were obtained from Reference 3 and are presented in Table 5.

3.3 MSFN STATIONS

The MSFN stations to support Apollo Applications Mission AAP-1/AAP-2 have not been officially identified. For trajectory simulation purposes, the MSFN stations to be used for Apollo Mission AS-503 (References 7 and 8)were assumed available except that the ship positions have been altered. The locations and capabilities of these stations are summarized in Table 6. MSFN station coordinates are referenced to the Fischer ellipsoid.

4. NOMINAL MISSION ANALYSIS AND DESCRIPTION

The description of Apollo Applications Mission AAP-1/2 resulting from the trajectory analysis performed during the preliminary mission planning is presented in this section.

4.1 FIRST PERIOD OF ACTIVITIES

The first period of activities for Apollo Applications Mission AAP-1/AAP-2 is initiated at 21:00 hours GMT (4:00 p.m. EST) on an assumed date, 15 January 1969, with the lift-off of AAP-1 from launch complex 34 at Cape Kennedy along a flight azimuth of 83 degrees. The S-IVB/CSM is inserted into an 81- by 110-nautical mile orbit approximately 595 seconds after lift-off.

At approximately 2 hours 22 minutes ground elapsed time (g. e.t.), an SPS maneuver to circularize the orbit at 110 nautical miles is performed at second apogee, immediately prior to acquisition by the Carnarvon tracking station.

The 110-nautical mile circular orbit provides a launch window the following day for a near inplane launch of the orbital workshop (OWS). A near inplane launch minimizes booster yaw steering and performance loss. This orbit also provides recurring launch opportunities for successive days (see Figure 5) with a similarly small yaw steering requirement. (Two launch opportunities a day for at least 4 days are desirable.)

Trajectory data pertinent to the first period of activities are presented in graphical and tabular form at the end of the text. Figure 6 shows the timeline from AAP-1 lift-off through the circularization maneuver as a function of g. e.t. Table 7 lists the periods of daylight and darkness up to the end of the rendezvous sequence. The ground tracks for the first 5 orbit revolutions are shown in Figure 7. MSFN acquisition and loss times for the CSM's first 20 revolutions are given in Table 8.

4.2 SECOND PERIOD OF ACTIVITIES

With the CSM coasting in the 110-nautical mile circular orbit, the second period of activities is initiated with the lift-off of AAP-2 from launch complex 37B on 16 January 1969, 20 hours, 24 minutes and 15 seconds GMT (approximately 23 hours 24 minutes g.e.t.) along an azimuth of 83.3 degrees.

Insertion of the OWS (AAP-2) into a 260-nautical mile circular orbit occurs approximately 588 seconds after lift-off and precedes the CSM by a 29.4-degree central angle. The S-IVB passivation sequence is initiated about 1 minute after OWS insertion, and consists of dumping the oxidizer and hydrogen fuel through the J-2 engine nozzle which produces an inplane impulse of approximately 45 feet per second. In order to minimize the required radial velocity component for the CSM at the coelliptic maneuver point, the OWS is pitched up 72 degrees from the local horizontal at the time of this passivation impulse. This results in an OWS orbit of 257 by 270 nautical miles with perigee shifted about 60 degrees west of the insertion point, thereby coinciding inertially with the desired maneuver line.

One hour, 23 minutes, and 6 seconds after OWS insertion, the CSM performs a phasing $(N_{C\,1})$ maneuver to initiate the rendezvous sequence. This maneuver at approximately 1 day 0 hour 56 minutes g. e. t. consists of a 17-second SM-RCS four jet ullage phase followed by a 10.4-second SPS thrusting period. The ΔV obtained from this burn is 242.8 feet per second and the resulting CSM orbit is 109 by 248 nautical miles. MSFN coverage is provided by the Mercury tracking ship.

About 45 minutes after the $N_{C\,1}$ maneuver, the CSM will perform a corrective combination (N_{CC}) maneuver. This maneuver is initiated at apogee of the orbit, (1 day 1 hour and 2 minutes g.e.t.), with a 17-second ullage maneuver followed by a 10.0-second SPS burn yielding a ΔV of 239.5 feet per second. The resultant CSM orbit is 247 by 248 nautical miles. The major purpose of the maneuver is to adjust the perigee height; however, any phase or planar dispersions, or both, will also be corrected at this point. The MSFN coverage will be provided by the Redstone tracking ship.

The coelliptical maneuver (N_{SR}) will be performed 45 minutes after the N_{C1} maneuver at approximately 1 day 2 hours 28 minutes g.e.t. This SM-RCS maneuver ($\Delta V = 21.1$ feet per second) is initiated at apogee and is designed to place the CSM on an ellipse that is coelliptic (the orbits apsides aligned) with that of the OWS. This coelliptic condition maintains a near-constant height differential of 10 nautical miles between the two orbits until after the TPI maneuver. The nominal N_{SR} maneuver was planned as an RCS burn for convenience so that the CSM crew can quickly resume optical tracking of the target; i.e., one man can remain in the navigation bay, which is not possible if the SPS is utilized. MSFN coverage is provided by the Hawaii tracking station.

Approximately 30 minutes following the N_{SR} maneuver, the terminal phase initiation (TPI) maneuver is performed at approximately 1 day 2 hours 58 minutes g.e.t. TPI is a 44.3-second RCS burn of 19.7-feet per second ΔV , which places the CSM on a trajectory that will intercept the OWS after 140 degrees of central angle travel. MSFN coverage during this burn will be provided by the Redstone tracking ship.

The terminal phase finalization (TPF) maneuver is initiated following a coast of 36 minutes 36 seconds after TPI at approximately 1 day 3 hours 35 minutes g.e.t., about 4 hours 11 minutes after OWS lift-off. This theoretical maneuver to rendezvous consists of 52.5 seconds of RCS burn, providing a ΔV of 23.3 feet per second.

Post-rendezvous stationkeeping and docking with the OWS will be covered by United States MSFN stations.

The trajectory data pertinent to the second period of activities are presented at the end of the text. Figure 8 presents a timeline of the major events of this second period of activities. Figure 9 shows the relative motion of AAP-1 and AAP-2 during the rendezvous. Figure 10 depicts the relative range and range rate between AAP-1 and AAP-2 as a function of g. e. t. The rendezvous orbit geometry of AAP-1/AAP-2 is shown in Figure 11. Tables 9 and 10 show the discrete events and the state vectors of the first two periods of activity, respectively. The ground tracks for revolutions 16 through 20 are shown in Figure 12. As noted previously,

the periods of daylight and darkness and the MSFN acquisition and loss times for the first two periods are presented in Tables 7 and 8.

4.3 THIRD PERIOD OF ACTIVITIES

The third period of activities will be devoted to performing experiments. Following the rendezvous and docking of the CSM with the orbital workshop, the vehicles coast in an elliptical orbit at an altitude of approximately 257 by 270 nautical miles for about 24.5 days. This period will be devoted to demonstrating the suitability of the spent S-IVB stage as a habitable space structure in the orbital workshop configuration and to evaluating the performance of orbital workshop crew operations for a mission duration up to 28 days. A preliminary description of the associated experiments is provided in Reference 1.

4.4 FOURTH PERIOD OF ACTIVITIES

Following the 24.5-day coast period and approximately 3 hours prior to the deorbit maneuver, the CSM separates from the orbital workshop. Approximately 10 minutes prior to the deorbit burn, the CSM is maneuvered into the proper retrograde attitude (pitched down 53.2 degrees from the local horizontal in the negative velocity vector direction). This attitude is 31.7 degrees below the line-of-sight vector to the horizon.

An SPS deorbit has been used in this preliminary mission plan. At a g.e.t. of approximately 25 days 11 hours 18 minutes, an SM-RCS ullage maneuver lasting 17 seconds is initiated. One second prior to completion of the ullage maneuver, the SPS is ignited and burns for 25.95 seconds. This SPS burn produces a ΔV of 709.2 feet per second and places the CSM on an ellipse that intersects the earth's atmosphere; a resultant inertial flight-path angle of 1.89 degrees below the local horizontal is achieved at the entry interface altitude of 400,000 feet. The deorbit sequence is designed so that splashdown occurs in the Western Atlantic primary recovery area at 60° West longitude to insure that debris from the SM does not fall on the mainland. The deorbit maneuver occurs in darkness. The deorbit maneuver must be initiated east of Hawaii to insure CM splashdown in the Western Atlantic recovery area. This precludes use of the Hawaii

tracking facilities and necessitates using a tracking ship for MSFN coverage of the deorbit maneuver.

A coast of 22.8 minutes follows the deorbit maneuver until the entry interface altitude is reached. Approximately 5 minutes prior to reaching this altitude, the SM is jettisoned, and the CM maneuvers to the desired entry orientation. The CM is in a retrograde attitude and pitched up approximately 21 degrees for entry.

At a g. e.t. of 25 days 12 hours 49 minutes 44 seconds, the CM reaches the atmospheric entry altitude of 400,000 feet with an inertial velocity magnitude and a flight-path angle of 25,983.3 feet per second and 1.89 degrees below the local horizontal, respectively.

The entry trajectory was established without the use of guidance. An average bank angle of 55 degrees was used to simulate the aerodynamics during the entry and, according to previous entry studies (Reference 9), results in CM splashdown near the center of the landing footprint.

Drogue chute deployment begins when the CM reaches an altitude of 23,500 feet. This event occurs 7 minutes 43 seconds after reaching the entry interface altitude.

Main chute deployment begins when the CM reaches an altitude of 10,200 feet. This event occurs 25 seconds after the drogue chute deployment.

The mission is terminated at a g.e.t. of 25 days 13 hours 0 minutes 21.7 seconds with CM splashdown at 21.2° North latitude and 59.5° West longitude.

The total earth relative range from entry interface altitude to splash-down is approximately 1295 nautical miles.

Trajectory data pertinent to this period of activities are presented in graphical and tabular form at the end of the text. Figure 1 depicts the major events from deorbit to splashdown, including the periods of daylight and darkness, and the available MSFN coverage, as a function of AAP-1

g. e. t. Figure 13 is an earth ground track of AAP-1 showing the CM entry and splashdown. Figure 14 is a longitude history of spacecraft inertial flight-path angle, altitude, and earth relative velocity from deorbit impulse to splashdown. Table 11 is a discrete events summary for the fourth period of activities.

4.5 SPS AND RCS PROPELLANT BUDGET

Table 2 represents a preliminary SPS and RCS propellant budget for the AAP-1/AAP-2 mission. Estimates of propellant usage for those events not generated in the trajectory simulation have been included to present a complete evaluation of the SPS-RCS propellant requirements. It can be seen that the propellant available is sufficient to support the AAP-1/2 mission.

Table 1a. AAP-1 Payload Weight Characteristics

<u>Item</u>	Predicted Weight (1b)

Nose Cone Jettison	-1000
Total Payload Weight Inserted Into Orbit	30368
Inert S-IVB Stage	21946
Instrumentation Unit (IU)	4300
Total AAP-2 Vehicle Weight In Orbit	56614

Note: Payload is defined as all components above the Instrumentation Unit plus weight of structural modifications to the S-IVB (including solar arrays) as required for the orbital workshop.

Table 2. AAP-1 SPS and RCS Propellant Budget
